

**Interference in thin films due to reflection**

**Colours of oil film on water**

**Colours of soap bubble**

**Interference of thin film**

**Interference by division of amplitude**

**DIVISION OF AMPLITUDE**

**If plane wave falls on a thin film then the wave reflected from the upper surface interferes with the wave reflected from the lower surface.**

**Thin films are material layers of about  $1\ \mu\text{m}$  thickness. For thin-film optics, the thickness of the layers of material must be on the order of the wavelengths of visible light. Layers at this scale can have remarkable reflective properties due to light wave interference.**

The optical path difference between the rays PQ and EH is

$$X = \mu(PF + FE) - PK$$

$$X = \mu(PN + NF + FE) - PK$$

Here  $\angle SPL = \angle LPK = i$

In  $\triangle EKP$ ,  $\angle KPE = \angle 90^\circ - i$

$$\angle EKP = \angle 90^\circ$$

so,  $\angle KEP = i$

Similarly in  $\triangle PNE$ ,  $\angle PEN = r$

$$\mu = \frac{\sin i}{\sin r} = \frac{PK/PE}{PN/PE} = \frac{PK}{PN}$$

Now,  $PK = \mu PN$

$$\therefore X = \mu (PN+NF+FE) - \mu PN$$

$$X = \mu(NF+FE)$$

EC is normal to OA. triangles ECF and FCL are congruent.

$$\begin{aligned} EC &= CL=t \text{ and } FE = FL \\ X &= \mu (NF+FL) \\ &= \mu NL \quad \dots\dots\dots(i) \end{aligned}$$

Angle between the inclined surfaces is the same as the angle  
Between the normals at P and F.

$$\text{SO, } \angle PRF = \theta$$

Again the exterior angle  $\angle PEJ$  of  $\Delta PRF$  is equal to the sum  
of the interior angles,

$$\angle PEJ = r + \theta$$

Now JR and EL are parallel and PEL cuts these parallel lines

$$\text{Such that } \angle FLC = \angle NFJ = r + \theta$$

In right angled triangle ENL ,

$$\begin{aligned} \cos (r + \theta) &= NL/EL \\ NL &= EL \cos (r + \theta) \\ NL &= 2t \cos (r + \theta) \end{aligned}$$

From equ (i),

$$x = 2\mu t \cos (r + \theta)$$

Since PQ is the reflected wave train from a denser medium  
Therefore there occurs a phase change of  $\pi$  or a path  
Difference of  $\lambda/2$ .

Effective path difference between the interfering  
waves PQ and EH is

$$\Delta = 2 \mu t \cos(r+\theta) - \lambda/2$$

**Condition for constructive interference**

$$2 \mu t \cos(r+\theta) - \lambda/2 = n\lambda$$
$$2 \mu t \cos(r+\theta) = (2n+1) \lambda/2 \dots\dots(1)$$

**Condition for destructive interference**

$$2 \mu t \cos(r+\theta) = n\lambda \dots\dots(2)$$

**From equ (1) and (2)**

$$t = \frac{(2n + 1) \frac{\lambda}{2}}{2\mu \cos(r + \theta)} \quad t = \frac{n\lambda}{2\mu \cos(r + \theta)}$$

**So bright and dark fringes of different orders will be observed at different thickness of the film.**

**Practically  $\theta$  is very small , therefore  $\cos(r + \theta) \approx \cos r$  and so the condition will be**

$$2 \mu t \cos r = (2n + 1) \lambda / 2 \quad \text{and} \quad 2 \mu t \cos r = n\lambda$$

- For monochromatic light beam incident on a wedge shaped film  $\mu$ ,  $\theta$  are constant. So change in path difference is only due to varying thickness of the film. At a particular point thickness is constant. So we get a bright or dark fringe at that point due to constant path difference.
- Thickness of the film continuously changes. So equidistant interference fringes are observed parallel to the line of intersection of the two surfaces means parallel to the edge of the wedge .

A diagram of a wedge-shaped air film. Two surfaces, \$AB\$ and \$AC\$, meet at point \$A\$. The angle between them is \$\theta\$. Points \$P\_n, P\_{n+1}, P\_{n+m}\$ are marked on surface \$AB\$, and points \$Q\_n, Q\_{n+1}, Q\_{n+m}\$ are marked on surface \$AC\$. Vertical lines connect \$P\_n\$ to \$Q\_n\$, \$P\_{n+1}\$ to \$Q\_{n+1}\$, and \$P\_{n+m}\$ to \$Q\_{n+m}\$. The thickness of the air film at \$P\_n\$ is labeled \$t\_n\$. A double-headed arrow below \$Q\_n\$ and \$Q\_{n+m}\$ indicates a distance \$x\$.

Suppose \$n\$th bright fringe at \$P\_n\$.

Thickness of airfilm will be at \$P\_n = P\_n Q\_n = t\_n\$

Relation for bright film will be

$$2 \mu t_n \cos(r+\theta) = (2n+1) \lambda/2$$

For nearly normal incidence  $\cos r = 1$

$$2 \mu t_n = (2n+1) \lambda/2 = 2 \mu P_n Q_n \dots\dots(3)$$

Next bright fringe will appear at  $P_{n+1}$  for  $n+1$ th fringe

$$2\mu P_{n+1} Q_{n+1} = [2(n+1)+1] \lambda/2 \dots\dots(4)$$

$$2\mu t_{n+1} = [2(n+1)+1] \lambda/2$$

Subtracting (3) from (4)

$$2\mu P_{n+1} Q_{n+1} - 2 \mu P_n Q_n = \lambda$$

$$P_{n+1} Q_{n+1} - P_n Q_n = \lambda/2\mu$$

$$t_{n+1} - t_n = \lambda/2\mu$$

$$\text{For air film } P_{n+1} Q_{n+1} - P_n Q_n = \lambda/2$$

$$P_{n+1} Q_{n+1} - P_n Q_n = \lambda/2$$

So next bright fringe will appear where air thickness will increase by  $\lambda/2$ .

For  $(n+m)$  th bright fringe

$$P_{n+m} Q_{n+m} - P_n Q_n = m\lambda/2$$

$$t_{n+m} - t_n = m\lambda/2$$

Therefore let at  $x$  distance from  $Q_n$   $m$  th bright fringe appears then

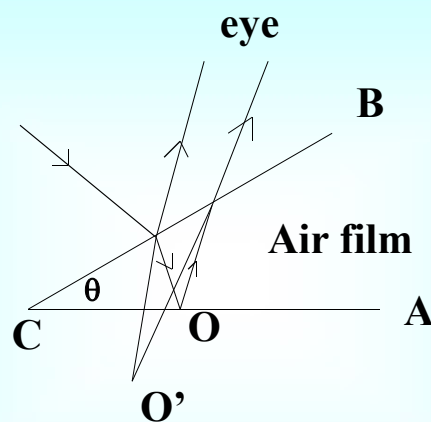

For small  $\theta$

$$\theta = \frac{P_{n+m}L}{P_n L} = \frac{P_{n+m}Q_{n+m} - P_n Q_n}{Q_n Q_{n+m}} = \frac{\frac{m\lambda}{2}}{x} = \frac{m\lambda}{2x}$$

$$\Rightarrow x = \frac{m\lambda}{2\theta}$$

Fringe width  $\beta = \frac{x}{m} = \frac{\lambda}{2\theta}$

The interfering rays do not enter the eye parallel to each other but they appear to diverge from a point near the film.
